

The impact of multimodal prehabilitation in colorectal cancer patients on postoperative lean body mass

MICHAEL HULL, M.S.(c), CISSN, PN

SUPERVISORS: DR. FRANCO CARLI, DR. HUGUES PLOURDE

COMMITTEE MEMBER: DR. CELENA SCHEEDE-BERGDAHL

FIGURE 1.2 Percent distribution of estimated new cancer cases, by sex, Canada, 2016

Males
102,900
New cases

Prostate	21.0%
Colorectal	14.1%
Lung and bronchus	14.0%

Females
99,500
New cases

Breast	25.8%
Lung and bronchus	14.1%
Colorectal	11.7%

Complications of Surgery

Postoperative complication rate of 21.1% to 30%

Associated Risk Factors

Functional capacity

Age

Lean mass

Poor nutrition status

Muscle strength

Over- or underweight

Complications of Surgery

Focus on modifiable risk factors

Associated Risk Factors

Functional Capacity

Legend

— Non-Prehabilitation

Santa Mina, D., C. Scheede-Bergdahl, C. Gillis and F. Carli (2015). "Optimization of surgical outcomes with prehabilitation." *Appl Physiol Nutr Metab* 40(9): 966-969.

Functional Capacity

Legend

— Non-Prehabilitation

Traditional Approach

Rehabilitation

- Efforts at accelerating recovery have focused on the postoperative period
- An inopportune time to alter nutrition and exercise
 - Patients are fatigued
 - Worried about exacerbating recovery
 - Stress/anxiety over additional treatments
- New approach: Prehabilitation before surgery

What Is Prehabilitation?

The process of augmenting a patient's functional capacity to optimize physiologic reserves so that they might withstand the stressor of inactivity associated with a surgical insult.

Components of Multimodal Prehab

**PERI OPERATIVE
PROGRAMME
PÉRI-OPÉRATOIRE**

• **Exercise**

• **Nutrition**

• **Anxiety
Management**

• **Smoking
Cessation**

Functional Capacity

Legend

— Non-Prehabilitation

The Importance of Lean Mass

Low lean body mass in CRC patients is correlated with:

- Increased postoperative complications
- Slowed recovery of bowel functions
- Extended hospital stays
- Higher re-admission rates and costs
- Higher levels of fatigue
- Reduced quality of life

The PREHAB Study

Study Design: International multicenter, prospective, randomized controlled trial (n=708). Our center is responsible for n=100.

Study Population: Adult (≥ 18) patients undergoing elective surgery for colorectal cancer at the Montréal General Hospital

The PREHAB Study

Intervention:

- **Intervention group:** Receives 4 weeks prehabilitation
- **Control group:** Receiving no prehabilitation
- **Both groups:** 8 weeks rehabilitation post-op (Enhanced Recovery After Surgery (ERAS) guidelines, which is standard care)

Study Questions & Objectives

- 1. What is the effect of a multimodal prehab program on lean mass accrual? Is the intervention providing a big enough stimulus to slow the loss of lean mass loss compared to control (standard care)?**
- 2. Are patients consuming enough protein in the postoperative period? Is there a carry-over effect in the intervention group? Is more intensive dietary counseling needed in the post-op window?**

Study Schedule

INTERVENTION GROUP

	Weeks Pre-Op				Operation	Weeks Post-Op	
Week	-4	-3	-2	-1	0	+4	+8
Schedule	Test Day			Test Day		Test Day	Test Day
	Exercise	Exercise	Exercise	Exercise			
	← ← Ongoing: Exercise/diet, protein supplement, smoking cessation → →						

CONTROL GROUP

	Weeks Pre-Op				Operation	Weeks Post-Op	
Week	-4	-3	-2	-1	0	+4	+8
Schedule	Test Day			Test Day		Test Day	Test Day
	← ← Ongoing: Exercise/diet, smoking cessation → →						

Exercise Intervention

	CONTROL	INTERVENTION
Exercise	<ul style="list-style-type: none">• Standard care• Unsupervised at home exercise like walks, stretching• Practice some deep breathing occasionally	<ul style="list-style-type: none">• Supervised high intensity training (HIT) and resistance training 3x/week• At home training 4x/week<ul style="list-style-type: none">• 60 minutes of low to moderate intensity exercise

Exercise Intervention

Exercise Dose (FITT)

- **F**requency – how often is the exercise performed
- **I**ntensity – how hard you exercise
- **T**ime – total duration
- **T**ype – the kind of exercise undertaken

Exercise Intervention

Participants will undergo a cardiopulmonary exercise test (CPET) and the exercise intensity will be individualized based on the CPET values.

- HIT = High-intensity interval training
- Performed for 28 minutes total on cycle ergometer
 - 4 intervals of moderate intensity (4 minutes @ $x > 90\%$ of VO_{2peak})
 - 4 intervals of high intensity (3 minutes @ 90% of VO_{2} anaerobic threshold)
- Rate Perceived Exertion (RPE) of 15-17 on Borg scale of 6-20

Exercise Intervention

Workload (W)

Exercise Intervention

Resistance training based on 1 repetition maximum (1RM) estimation

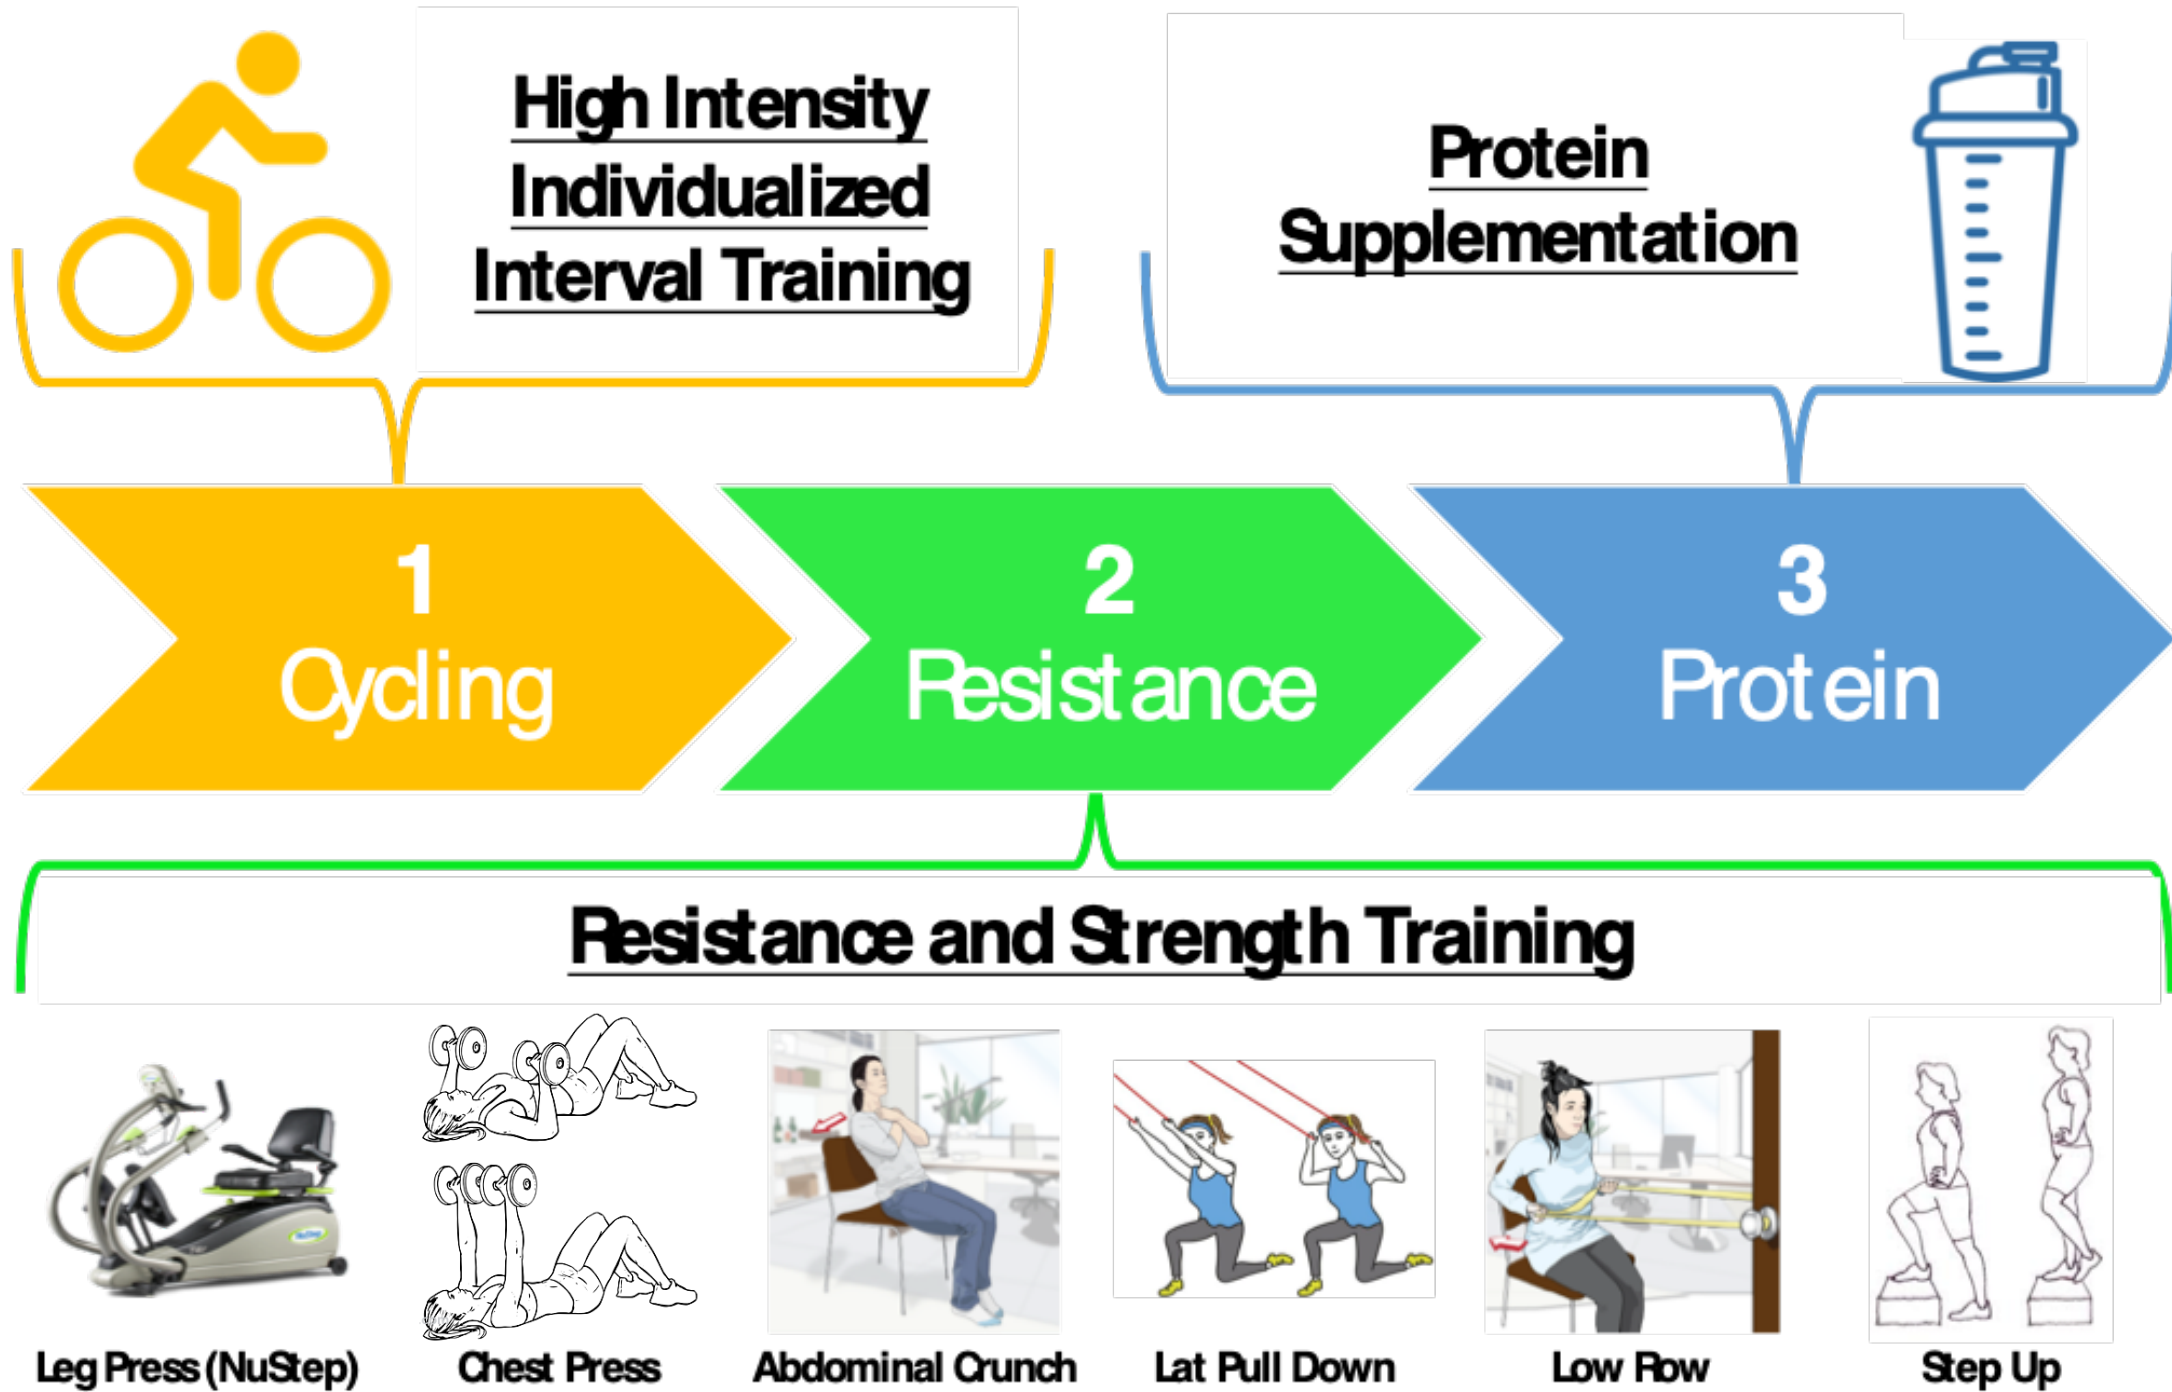

- 2 sets of 10 repetitions of 6 exercises:
 - **Leg press** – performed on NuStep with resistance on
 - **Chest press** – on a flat bench with dumbbells
 - **Abdominal crunch** – seated or, if possible, supine on the floor
 - **Lat pull down** – using resistance bands attached to elevated hook
 - **Low row** – seated, with resistance bands
 - **Step up** – performed on 18.5 cm platform

Exercise Intervention

- **Volume will be progressively increased week over week**
 - In week 1 using 65% of calculated 1RM (baseline)
 - In week 2 using 70% of calculated 1RM (baseline)
 - In week 3 using 65% of calculated 1RM (at 3 weeks)
 - In week 4 using 70% of calculated 1RM (at 3 weeks)
- **Progress will be tracked via total volume per week**
 - Volume load = sets * repetitions * weight used

In-Hospital Training

Nutrition Intervention

	CONTROL	INTERVENTION
DIET	<ul style="list-style-type: none">• Try to eat well throughout the day• Follow the recommendations given to you by your dietitian	<ul style="list-style-type: none">• Increase protein to 1.5-1.8 g/kg/day• Consume protein before bed• Balance out protein intake between meals• Consume protein drink within 30 minutes of in-hospital workouts• Provide whey protein isolate supplement as needed

Nutrition Intervention

- **Nutritional status will be tracked using the PG-SGA**
 - Four screenings at -4, -1, +4, and +8
 - Appropriate nutritional advise will be given regardless of group
- **Intake will be tracked using 3-day food diaries and 24-hour recall**
 - Four 3-day food diaries at -4, -1, +4, and +8
 - Three 24-hour recalls take postoperatively at +1, +2, and 3+ weeks

Lean Mass Assessment

- **Body composition assessment via DXA scan at -4, -1, +4, and +8**
- **Standardized testing procedures**
 - Same or similar clothing
 - In the morning after overnight fast, if possible.
 - No exercise prior
 - Hydrated (but not over- or dehydrated)
 - No recent major dietary changes in the 3 days prior
 - Same equipment, software, technician, and body position

CONTROL & INTERVENTION

Psychological Coping

Patients receive 1.5 hours of instruction in the first session and more sessions during the 4 weeks of prehabilitation if necessary. The goal is to provide anxiety reduction and avoid depression.

Smoking Cessation

Intensive counseling and nicotine replacement therapy (NRT) will be offered to all patients during the 4 weeks prior to the surgery.

Statistical Analysis

The sample size calculation is based on the primary outcome of differences in lean body mass. An α of 0.05, β of 0.2, and power of 0.80 (two-sided test) will be used with an expected dropout rate of 10%. Sample size needed would be 36 participants, 18 per group.

A one-way repeated measures ANOVA will be used to determine the effect of treatment on lean body mass and protein intake differences between groups. Statistical significance is defined as $p < 0.05$.

Significance

Results will provide data that may be useful to examine if current PREHAB approaches are resulting in sufficient lean mass accretion and preservation.

Additionally, we can examine patient protein intake post-op to see if future approaches may need to be altered to increase odds of favorable outcomes.
